Abstract:

Skin metastasis is a relatively rare complication of pulmonary carcinoma. The clinical features are varied and can present as sclerodermoid, bullous, erysipeloid, or alopecia, but they can also manifest as skin nodules, as in our case. We report a case of a 66-year-old man exhibiting this unusual manifestation. This case report aims to review and describe different findings in ultrasound, CT and pathology, to establish the diagnosis of pulmonary carcinoma manifested by skin metastasis.

Biography:

I was born in Rabat, Morocco. I commenced my medical studies in 2014 after obtaining a specialized Scientific Baccalaureate in Biology.

In 2022, I embarked on my journey into radiology as an intern and later pursued a residency in radiology in 2023. Throughout my residency, I gained experience in various subspecialties including emergency radiology, pediatric radiology, gynecological and obstetric radiology, neuroradiology, and oncological radiology. I actively engaged in research projects within the radiology team.

I have undertaken medical exchange programs in general medicine (in Italy at Messina and in Germany at Heidelberg) and in radiology (in Brazil at Botucatu and in Mexico at Monterrey). I actively participated in Moroccan radiology conferences, including those organized by the Moroccan Society of Radiology and the Franco-Maghrebian Radiologists' Group, as well as the Francophone Radiology Days in France.

I have contributed to several research projects in collaboration with my professors and colleagues in the field of oncological radiology.
